

Distorting Mixed Tsirelson Spaces*

G. Androulakis[†]

E. Odell[‡]

Abstract: Any regular mixed Tsirelson space $T(\theta_n, S_n)_\mathbb{N}$ for which $\frac{\theta_n}{\theta^n} \rightarrow 0$, where $\theta = \lim_n \theta_n^{1/n}$, is shown to be arbitrarily distortable. Certain asymptotic ℓ_1 constants for those and other mixed Tsirelson spaces are calculated. Also a combinatorial result on the Schreier families $(S_\alpha)_{\alpha < \omega_1}$ is proved and an application is given to show that for every Banach space X with a basis (e_i) , the two Δ -spectrums $\Delta(X)$ and $\Delta(X, (e_i))$ coincide.

1 Introduction

A Banach space X with basis (e_i) is asymptotic ℓ_1 if there exists $\delta > 0$ such that for all n and block bases $(x_i)_1^n$ of $(e_i)_n^\infty$,

$$\left\| \sum_{i=1}^n x_i \right\| \geq \delta \sum_{i=1}^n \|x_i\|. \quad (1)$$

Such a space need not contain ℓ_1 as witnessed by Tsirelson's famous space T . The complexity of the asymptotic ℓ_1 structure within X can be measured by certain constants $\delta_\alpha(e_i)$ for $\alpha < \omega_1$. $\delta_1(e_i)$ is the largest $\delta > 0$ satisfying (1) above. Subsequent δ_α 's are defined by a similar formula where $(x_i)_1^n$ ranges over " α -admissible" block bases (all terms are precisely defined in section 2). These notions were developed in [OTW] where, in addition, $\delta_\alpha(y_i)$ was considered, for a block basis (y_i) of (e_i) . In this setting, (y_i) becomes the reference frame and one naturally has $\delta_\alpha(y_i) \geq \delta_\alpha(e_i)$. These constants can perhaps increase by passing to further block bases and this leads to the notion of the Δ -spectrum of X , $\Delta(X)$. Roughly, $\Delta(X)$ is the set of all $\gamma = (\gamma_\alpha)_{\alpha < \omega_1}$ where γ_α is the stabilization of $\delta_\alpha(y_i)$ for (y_i) some block basis of (e_i) . Alternatively by keeping (e_i) as the reference frame, in a similar manner we obtain $\Delta(X, (e_i))$. In section 3 we prove that these two notions coincide, $\Delta(X) = \Delta(X, (e_i))$.

Argyros and Deliyanni [AD] constructed the first example of an asymptotic ℓ_1 arbitrarily distortable Banach space by constructing "mixed Tsirelson spaces" and proving that such spaces can be arbitrarily distortable. In section 4 we consider the simplest class of mixed Tsirelson spaces $X = T(\theta_n, S_n)_{n \in \mathbb{N}}$ where $\theta_n \rightarrow 0$ and $\sup_n \theta_n < 1$. These are reflexive asymptotic ℓ_1 spaces having a 1-unconditional basis (e_i) . Also we may assume $\theta \equiv \theta_n^{1/n}$ exists. We prove that if $\frac{\theta_n}{\theta^n} \rightarrow 0$ then X is arbitrarily distortable. In particular, this happens if $\theta = 1$. Thus, for example, $T(\frac{1}{n+1}, S_n)_\mathbb{N}$ is an arbitrarily distortable space. We also calculate the asymptotic constants $\ddot{\delta}_\alpha(X)$ for these spaces along with the spectral index $I_\Delta(X)$. $\ddot{\delta}_\alpha(X)$ is the supremum of $\delta_\alpha((x_i), |\cdot|)$ under all equivalent norms on X and $I_\Delta(X)$ is the first ordinal α for which $\ddot{\delta}_\alpha(X) < 1$.

**Keywords* : Schreier families, Δ -spectrum, mixed Tsirelson norms, arbitrarily distortable Banach space.

2 Preliminaries

$X, Y, Z, \dots$ shall denote separable infinite dimensional Banach spaces. *All the spaces we consider will have bases.* Every Banach space with a basis can be viewed as the completion of c_{00} (the linear space of finitely supported real valued sequences) under a certain norm. (e_i) will denote the unit vector basis for c_{00} and whenever a Banach space $(X, \|\cdot\|)$ with a basis is regarded as the completion of $(c_{00}, \|\cdot\|)$, (e_i) will denote this (normalized) basis. If $x \in c_{00}$ and $E \subseteq \mathbf{N}$, $Ex \in c_{00}$ is the restriction of x to E ; $Ex(j) = x(j)$ if $j \in E$ and 0 otherwise. Also the *support* of x , $\text{supp}(x)$, (w.r.t. (e_i)) is the set $\{j \in \mathbf{N} : x(j) \neq 0\}$. The *range* of x , $\text{ran}(x)$, (w.r.t. (e_i)) is the smallest interval which contains $\text{supp}(x)$. If $x, x_1, x_2, \dots$ are vectors in X (and $k \in \mathbf{N}$) then we say that x is an average of $(x_i)_i$ (of length k) if there exists $F \subset \mathbf{N}$ with $x = \frac{1}{|F|} \sum_{i \in F} x_i$ (and $|F| = k$).

We say that a sequence (y_i) is a (*convex*) *block sequence* of (x_i) if for all i , $y_i = \sum_{j=m_i}^{m_{i+1}-1} \alpha_j x_j$ for some sequence $m_1 < m_2 < \dots$, of integers and $(\alpha_j)_{j \in \mathbf{N}} \subset \mathbf{R}$ (resp. with $\alpha_j \geq 0$ for all j , and $\sum_{j=m_i}^{m_{i+1}-1} \alpha_j = 1$ for all i). If (x_i) is a block basis of (y_i) we write $(x_i) \prec (y_i)$. $X \prec Y$ shall mean that X has a basis which is a block basis of a certain basis for Y , when the given bases are understood. For $\lambda > 1$, $(X, \|\cdot\|)$ is λ -*distortable* if there exists an equivalent norm $|\cdot|$ on X so that for all $Y \prec X$

$$D(Y, |\cdot|) \equiv \sup\left\{\frac{|y|}{|z|} : y, z \in Y, \|y\| = \|z\| = 1\right\} \geq \lambda.$$

X is *distortable* if it is λ -distortable for some $\lambda > 1$ and *arbitrarily distortable* if it is λ -distortable for all $\lambda > 1$. X is of *D-bounded distortion* if for all equivalent norms $|\cdot|$ on X and for all $Z \prec X$ there exists $Y \prec Z$ with $D(Y, |\cdot|) \leq D$. Note that if $C = \inf\{\frac{\|y\|}{|y|} : y \in Y, y \neq 0\}$ then

$$C |y| \leq \|y\| \leq D(Y, |\cdot|) C |y| \text{ for all } y \in Y. \quad (2)$$

For more information on distortion we recommend the reader consult the following papers: [S], [MT], [OS1], [OS2], [OS3], [Ma], [T], [OTW].

Asymptotic ℓ_1 Banach spaces are defined by (1) in section 1 (for another approach to asymptotic structure see [MMT]). These spaces were studied in [OTW] where certain asymptotic constants were introduced. We shall recall the relevant definitions but first we need to recall the definition of the Schreier sets S_α , $\alpha < \omega_1$ [AA]. For $F, G \subset \mathbf{N}$, we write $F < G$ when $\max(F) < \min(G)$ or one of them is empty, and we write $n \leq F$ instead of $\{n\} \leq F$. Also for $x, y \in c_{00}$, $x < y$ means $\text{ran}(x) < \text{ran}(y)$.

Definition 2.1 $S_0 = \{\{n\} : n \in \mathbf{N}\} \cup \{\emptyset\}$. If $\alpha < \omega_1$ and S_α has been defined, $S_{\alpha+1} = \{\cup_1^n F_i : n \in \mathbf{N}, n \leq F_1 < F_2 < \dots < F_n \text{ and } F_i \in S_\alpha \text{ for } 1 \leq i \leq n\}$. If α is a limit ordinal choose $\alpha_n \nearrow \alpha$ and set $S_\alpha = \{F : n \leq F \in S_{\alpha_n} \text{ for some } n\}$.

If $(E_i)_1^\ell$ is a finite sequence of non-empty subsets of $\mathbf{N}$ and $\alpha < \omega_1$ then we say that $(E_i)_1^\ell$ is α -*admissible* if $E_1 < \dots < E_\ell$ and $(\min E_i)_1^\ell \in S_\alpha$. If (e_i) is a basic sequence and $(x_i)_1^\ell \prec (e_i)$ then $(x_i)_1^\ell$ is α -*admissible with respect to* (e_i) if $(\text{ran}(x_i))_1^\ell$ is α -admissible where the range of x , $\text{ran}(x)$, is w.r.t. (e_i) . If $x \in \text{span}(x_i)$, then x is α -*admissible w.r.t.* (x_i) if $\text{supp}(x)$ (w.r.t. (x_i)) $\in S_\alpha$. Also if $x \in \text{span}(x_i)$ then x is a *1-admissible average* of (x_i) w.r.t. (e_i) if there exists a finite set $F \subset \mathbf{N}$ such that $x = \frac{1}{|F|} \sum_{i \in F} x_i$ and $(x_i)_{i \in F}$ is 1-admissible w.r.t. (e_i) . Note that if x is a

1-admissible average of (x_i) w.r.t. (e_i) and for some $\alpha < \omega_1$ each x_i is α -admissible w.r.t. (e_i) then x is $\alpha + 1$ -admissible w.r.t. (e_i) . Thus if (x_i) is a basis for X then X is asymptotic ℓ_1 iff

$$0 < \delta_1(x_i) \equiv \delta_1(X) \equiv \delta_1(X, \|\cdot\|) = \sup \{ \delta \geq 0 : \|\sum_1^n y_i\| \geq \delta \sum_1^n \|y_i\| \text{ whenever } (y_i)_1^n \prec (x_i) \text{ and } (y_i)_1^n \text{ is 1-admissible w.r.t. } (x_i) \}.$$

In [OTW] this definition was extended as follows: For $\alpha < \omega_1$

$$\delta_\alpha(x_i) \equiv \delta_\alpha(X) \equiv \delta_\alpha(X, \|\cdot\|) = \sup \{ \delta \geq 0 : \|\sum_1^n y_i\| \geq \delta \sum_1^n \|y_i\| \text{ whenever } (y_i)_1^n \prec (x_i) \text{ and } (y_i)_1^n \text{ is } \alpha\text{-admissible w.r.t. } (x_i) \}.$$

Observation 2.2 *Note that if we have two equivalent norms $\|\cdot\|$, $\|\!\|\!\cdot\!\|$ on X and for some $c, C > 0$, $c\|x\| \leq \|x\| \leq C\|x\|$ for all $x \in X$, then for all $\alpha < \omega_1$,*

$$\frac{c}{C} \delta_\alpha(X, \|\!\cdot\!\|) \leq \delta_\alpha(X, \|\cdot\|) \leq \frac{C}{c} \delta_\alpha(X, \|\cdot\|).$$

In problems of distortion one is concerned with block bases and equivalent norms. Thus we also consider [OTW]

$$\begin{aligned} \dot{\delta}_\alpha(x_i) &= \sup \{ \delta_\alpha(y_i) : (y_i) \prec (x_i) \} \text{ and} \\ \ddot{\delta}_\alpha(x_i) &= \sup \{ \dot{\delta}_\alpha((x_i), |\cdot|) : |\cdot| \text{ is an equivalent norm on } X \}. \end{aligned}$$

If $(y_i) \prec (x_i)$ then $\delta_\alpha(y_i) \geq \delta_\alpha(x_i)$. This is because each S_α is *spreading* (if $(n_i)_1^k \in S_\alpha$ and $m_1 < \dots < m_k$ with $n_i \leq m_i$ for all $i = 1, \dots, k$, then $(m_i)_1^k \in S_\alpha$). This leads to the following definition [OTW].

Definition 2.3 *A basic sequence (y_i) Δ -stabilizes $\gamma = (\gamma_\alpha)_{\alpha < \omega_1} \subseteq \mathbb{R}$ if there exists $\varepsilon_n \searrow 0$ so that for all $\alpha < \omega_1$ there exists $m \in \mathbb{N}$ so that for all $n \geq m$ if $(z_i) \prec (y_i)_n^\infty$ then $|\delta_\alpha(z_i) - \gamma_\alpha| < \varepsilon_n$.*

Remark It is automatic from the definition that if (y_i) Δ -stabilizes γ then for all $\alpha < \omega_1$, $\gamma_\alpha = \sup \{ \delta_\alpha(z_i) : (z_i) \prec (y_i) \}$. Furthermore if $(z_i) \prec (y_i)$ then (z_i) Δ -stabilizes γ .

It is shown in [OTW] that if X has a basis (x_i) and $(y_i) \prec (x_i)$ then there exists $(z_i) \prec (y_i)$ and $\gamma = (\gamma_\alpha)_{\alpha < \omega_1}$ so that (z_i) Δ -stabilizes γ .

Definition 2.4 *Let X have a basis (x_i) . The Δ -spectrum of X , $\Delta(X)$, is defined to be the set of all γ 's so that (y_i) stabilizes γ for some $(y_i) \prec (x_i)$. We also define $\ddot{\Delta}(X) = \cup \{ \Delta(X, |\cdot|) : |\cdot| \text{ is an equivalent norm on } X \}$.*

We have that $\Delta(X) \neq \emptyset$ and it is easy to see that $\ddot{\delta}_\alpha(X) = \sup \{ \gamma_\alpha : \gamma \in \ddot{\Delta}(X) \}$

Theorem 2.5 [OTW] *Let X have a basis (x_i) .*

1. *If $\gamma \in \Delta(X)$ then γ_α is a continuous decreasing function of α . Also $\gamma_{\alpha+\beta} \geq \gamma_\alpha \gamma_\beta$ for all $\alpha, \beta < \omega_1$.*

2. For all $\alpha < \omega_1$ and $n \in \mathbf{N}$, $\ddot{\delta}_{\alpha \cdot n}(X) = (\ddot{\delta}_\alpha(X))^n$.
3. X does not contain ℓ_1 iff $\ddot{\delta}_\alpha(X) = 0$ for some $\alpha < \omega_1$.

Definition 2.6 Let X have a basis (x_i) . The spectral index $I_\Delta(X)$ is defined by $I_\Delta(X) = \inf\{\alpha < \omega_1 : \ddot{\delta}_\alpha(X) < 1\}$ if such an α exists and $I_\Delta(X) = \omega_1$, otherwise.

Definition 2.7 Mixed Tsirelson Norms [AD] Let $F \subseteq \mathbf{N}$. Let $(\alpha_n)_{n \in F}$ be a set of countable ordinals and $(\theta_n)_{n \in F} \subset (0, 1)$. The mixed Tsirelson space $T(\theta_n, S_{\alpha_n})_{n \in F}$ is the completion of c_{00} under the implicit norm

$$\|x\| = \|x\|_\infty \vee \sup_{q \in \mathbf{N}} \sup \left\{ \theta_q \sum_1^n \|E_i x\| : (E_i)_1^n \text{ is an } \alpha_q\text{-admissible sequence of sets} \right\}.$$

It is proved in [AD] that such a norm exists. They also proved that $T(\theta_n, S_{\alpha_n})_{n \in F}$ is reflexive if F is finite or $\lim_{F \ni n \rightarrow \infty} \theta_n = 0$. (e_n) is a 1-unconditional basis for $T(\theta_n, S_{\alpha_n})$ so we can restrict the E_i 's in the above definition to be *intervals*. It is worth noting that T , Tsirelson's space [Ts] as described in [FJ] satisfies $T = T(1/2, S_1) = T(1/2^n, S_n)_\mathbf{N}$.

3 A property of the Δ -spectrum

The definition of $\delta_\alpha(x_i)$ is w.r.t. the coordinate system (x_i) . In [OTW] the following notion is also introduced:

Definition 3.1 Let (e_i) be a basis for X and let $(x_i) \prec (e_i)$. For $\alpha < \omega_1$ we define

$$\delta_\alpha((x_i), (e_i)) = \sup \left\{ \delta \geq 0 : \left\| \sum_1^n y_i \right\| \geq \delta \sum_1^n \|y_i\| \text{ whenever } (y_i)_1^n \prec (x_i) \text{ and } (y_i)_1^n \text{ is } \alpha\text{-admissible w.r.t. } (e_i) \right\}.$$

If $(y_i) \prec (e_i)$ we say that (y_i) $\Delta_{(e_i)}$ -stabilizes $\gamma = (\gamma_\alpha)_{\alpha < \omega_1}$ if there exists $\varepsilon_n \searrow 0$ so that for all $\alpha < \omega_1$ there exists $m \in \mathbf{N}$ so that if $n \geq m$ and $(z_i) \prec (y_i)_n^\infty$ then $|\delta_\alpha((z_i), (e_i)) - \gamma_\alpha| < \varepsilon_n$. Let $\Delta(X, (e_i))$ be the set of all γ 's so that (y_i) $\Delta_{(e_i)}$ -stabilizes γ for some $(y_i) \prec (e_i)$.

One can show, by the same arguments used to establish the analogous result for $\Delta(X)$ [OTW], that for all $(x_i) \prec (e_i)$ there exists $(y_i) \prec (x_i)$ and $\gamma = (\gamma_\alpha)_{\alpha < \omega_1}$ so that (y_i) $\Delta_{(e_i)}$ -stabilizes γ . In particular, $\Delta(X, (e_i))$ is non-empty.

In this section we prove that the Δ -stabilization and the $\Delta_{(e_i)}$ -stabilization are actually the same notions. More precisely we prove

Theorem 3.2 Let X have a basis (e_i) and let $(x_i) \prec (e_i)$ so that (x_i) $\Delta_{(e_i)}$ -stabilizes $\bar{\gamma} \in \Delta(X, (e_i))$ and (x_i) Δ -stabilizes $\gamma \in \Delta(X)$. Then $\bar{\gamma} = \gamma$. Hence $\Delta(X) = \Delta(X, (e_i))$.

First we need a combinatorial result. $[\mathbf{N}]$ denotes the set of infinite subsequences of $\mathbf{N}$. If $N = (n_i) \in [\mathbf{N}]$ then $S_\alpha(N) = \{(n_i)_{i \in F} : F \in S_\alpha\}$ and $[N]$ is the set of infinite subsequences of N .

Proposition 3.3 *Let $N \in [\mathbb{N}]$. Then there exists $L = (\ell_i) \in [N]$ so that for all $\alpha < \omega_1$,*

$$(\ell_i)_{i \in F} \in S_\alpha \Rightarrow (\ell_{i+1})_{i \in F} \in S_\alpha(N).$$

Proof Let $N = (n_i)$. We shall choose $M = (m_i) \in [N]$ and then prove by induction on α that $L = (\ell_i)$ satisfies the proposition where $\ell_i = n_{m_i}$. Let $m_1 = n_1$. If m_k has been defined set $m_{k+1} = n_{m_k}$.

The case $\alpha = 0$ is trivial.

Assume the result holds for α and that $(n_{m_i})_{i \in F} \in S_{\alpha+1}$. Thus there exists $k \in \mathbb{N}$ and $n_{m_k} \leq E_1 < E_2 < \dots < E_{n_{m_k}}$ (some possibly empty) so that $E_j \in S_\alpha$ for all j and $(n_{m_i})_{i \in F} = \cup_1^{n_{m_k}} E_j$. For each j let $E_j = (n_{m_i})_{i \in F_j}$. Then $n_{n_{m_k}} = n_{m_{k+1}} \leq (n_{m_{i+1}})_{i \in F} = \cup_1^{n_{m_k}} (n_{m_{i+1}})_{i \in F_j}$ and for all j , $(n_{m_{i+1}})_{i \in F_j} \in S_\alpha(N)$. Therefore $(n_{m_{i+1}})_{i \in F} \in S_{\alpha+1}(N)$.

If α is a limit ordinal and $\alpha_n \nearrow \alpha$ are the ordinals used to define S_α and the result holds for all $\beta < \alpha$ (so in particular for each α_n), let $(n_{m_i})_{i \in F} \in S_\alpha$. Thus for some $k \in \mathbb{N}$, $k \leq \min(n_{m_i})_{i \in F} \equiv n_{m_{i_0}} \leq (n_{m_i})_{i \in F} \in S_{\alpha_k}$. Hence $n_k \leq n_{n_{m_{i_0}}} = n_{m_{i_0+1}} \leq (n_{m_{i+1}})_{i \in F} \in S_{\alpha_k}(N)$ therefore $(n_{m_{i+1}})_{i \in F} \in S_\alpha(N)$. $\square$

As a corollary we obtain a result of independent interest.

Corollary 3.4 *Let $N \in [\mathbb{N}]$. Then there exists $L = (\ell_i) \in [N]$ so that for all $\alpha < \omega_1$,*

$$(\ell_i)_{i \in F} \in S_\alpha \Rightarrow (\ell_i)_{i \in F \setminus \min(F)} \in S_\alpha(N).$$

Proof Let L be as in proposition 3.3. Let $F = (f_1 < f_2 < \dots < f_r)$ with $(\ell_i)_{i \in F} \in S_\alpha$. Thus $(\ell_{f_1+1}, \ell_{f_2+1}, \dots, \ell_{f_r+1}) \in S_\alpha(N)$. Since $f_1 + 1 \leq f_2$, $f_2 + 1 \leq f_3, \dots$ and $S_\alpha(N)$ is both spreading and hereditary we get that $(\ell_i)_{i \in F \setminus \min(F)} \in S_\alpha(N)$. $\square$

Proof of theorem 3.2 Let $(x_i) \Delta_{(e_i)}$ - and Δ -stabilize $\bar{\gamma}$ and γ respectively and let $\alpha < \omega_1$. Since S_α is spreading, $\bar{\gamma} \leq \gamma$. Let $\varepsilon > 0$ and choose $(y_i) \prec (x_i)$ so that for all $(z_i) \prec (y_i)$,

$$|\delta_\alpha(z_i) - \gamma_\alpha| < \varepsilon.$$

For $i \in \mathbb{N}$ set $n_i = \min(\text{ran}(y_i))$ w.r.t. (e_i) and choose $L = (n_{m_i})$ by proposition 3.3. For $w \in \text{span}(y_{m_i})$ if $w = \sum_{i=j}^\ell a_i y_{m_i}$ where $a_j \neq 0$ we set $\bar{w} = \sum_{i=j+1}^\ell a_i y_{m_i}$.

Claim: If $(w_i)_1^\ell \prec (y_{m_i})$ is α -admissible w.r.t. (e_j) then $(\bar{w}_i)_1^\ell$ is α -admissible w.r.t. (y_j) .

Indeed let $m_{k_i} = \min(\text{ran}(w_i))$ w.r.t. (y_j) . Then $n_{m_{k_i}} = \min(\text{ran}(w_i))$ w.r.t. (e_j) , and $(n_{m_{k_i}})_1^\ell \in S_\alpha \Rightarrow (n_{m_{k_i+1}})_1^\ell \in S_\alpha((n_j)) \Rightarrow (m_{k_i+1})_1^\ell \in S_\alpha$. Since $m_{k_i+1} \leq \min(\text{ran}(\bar{w}_i))$ w.r.t. (y_j) , and S_α is spreading the claim follows.

We may assume that $\|y_{m_i}\| = 1$ for all i and that no subsequence of (y_{m_i}) is equivalent to the unit vector basis of c_0 (indeed, if this were false then clearly $\bar{\gamma}_0 = \gamma_0 = 1$ and $\bar{\gamma}_\alpha = \gamma_\alpha = 0$ for all $\alpha \geq 1$). Thus by taking long averages of (y_{m_i}) we may choose $(z_i) \prec (y_{m_i})$ with the property that for all $z \in \text{span}(z_i)$

$$\|z - \bar{z}\| < \varepsilon \|\bar{z}\|.$$

By the definition of $\bar{\delta}_\alpha \equiv \delta_\alpha((z_i), (e_i))$ there exists $(w_i)_1^\ell \prec (z_i)$ which is α -admissible w.r.t. (e_j) and satisfies

$$\left\| \sum_1^\ell w_i \right\| < (\bar{\delta}_\alpha + \varepsilon) \sum_1^\ell \|w_i\|.$$

By the above claim $(\bar{w}_i)_1^\ell$ is α -admissible w.r.t. (y_j) . Furthermore

$$\begin{aligned} \left\| \sum_1^\ell \bar{w}_i \right\| &\leq \left\| \sum_1^\ell w_i \right\| + \sum_1^\ell \|w_i - \bar{w}_i\| < (\bar{\delta}_\alpha + \varepsilon) \sum_1^\ell \|w_i\| + \sum_1^\ell \varepsilon \|w_i\| \\ &< [(\bar{\delta}_\alpha + \varepsilon)(1 + \varepsilon) + \varepsilon] \sum_1^\ell \|w_i\|. \end{aligned}$$

It follows that $\gamma_\alpha - \varepsilon < \delta_\alpha(y_i) < (\bar{\gamma}_\alpha + \varepsilon)(1 + \varepsilon) + \varepsilon$. Since ε is arbitrary we obtain $\gamma_\alpha \leq \bar{\gamma}_\alpha$ and so $\gamma_\alpha = \bar{\gamma}_\alpha$.

To prove that $\Delta(X) = \Delta(X, (e_i))$, let's first show the inclusion $\subseteq$. Let (x_i) Δ -stabilize $\gamma \in \Delta(X)$. We can find $(y_i) \prec (x_i)$ that $\Delta_{(e_i)}$ -stabilizes $\bar{\gamma} \in \Delta_{(e_i)}$. But then (y_i) Δ -stabilizes γ , therefore $\gamma = \bar{\gamma}$, thus $\gamma \in \Delta_{(e_i)}$. The inclusion $\supseteq$ is proved similarly. $\square$

4 The space $T(\theta_n, S_n)_\mathbb{N}$

If $\theta_n \not\rightarrow 0$ or if $\theta_n = 1$ for some n then $T(\theta_n, S_n)_\mathbb{N}$ is isomorphic to ℓ_1 . Thus we shall confine ourselves to the case where $\sup \theta_n < 1$ and $\theta_n \rightarrow 0$. Furthermore we assume that $\theta_n \searrow 0$ and $\theta_{m+n} \geq \theta_n \theta_m$ for all $n, m \in \mathbb{N}$. Indeed it is easy to see that $T(\theta_n, S_n)_\mathbb{N}$ is naturally isometric to $T(\bar{\theta}_n, S_n)_\mathbb{N}$ where

$$\bar{\theta}_n \equiv \sup \left\{ \prod_{i=1}^\ell \theta_{k_i} : \sum_{i=1}^\ell k_i \geq n \right\}.$$

Definition 4.1 A sequence (θ_n) of scalars is called *regular* if $(\theta_n) \subset (0, 1)$, $\theta_n \searrow 0$ and $\theta_{n+m} \geq \theta_n \theta_m$ for all $n, m \in \mathbb{N}$. If the sequence (θ_n) is regular we define the space $T(\theta_n, S_n)_\mathbb{N}$ to be *regular*.

Throughout this section, the spaces $T(\theta_n, S_n)_\mathbb{N}$ will always be assumed to be regular.

It is easy to see (eg [OTW]) that if a sequence $(b_n) \subset (0, 1]$ satisfies $b_{n+m} \geq b_n b_m$ for all $n, m \in \mathbb{N}$ then $\lim_n b_n^{1/n}$ exists and equals $\sup_n b_n^{1/n}$. Therefore, if the sequence (θ_n) is regular then the limit $\theta \equiv \lim_{n \rightarrow \infty} \theta_n^{1/n} = \sup_n \theta_n^{1/n}$ exists. Note also that if $(X, \|\cdot\|)$ is a Banach space with a basis, then $\delta_{n+m}(X) \geq \delta_n(X) \delta_m(X)$ for all $n, m \in \mathbb{N}$, thus $\lim_n \delta_n(X)^{1/n} = \sup_n \delta_n(X)^{1/n}$ exists. Furthermore, if X does not contain ℓ_1 isomorphically, then $1 > \delta_n(X) \searrow 0$.

For $n \in \mathbb{N}$, define $\phi_n \equiv \frac{\theta_n}{\theta^n}$. We easily see

- If $\theta = 1$ then $\phi_n = \theta_n \searrow 0$.
- $\phi_{n+m} \geq \phi_n \phi_m$ for all $n, m \in \mathbb{N}$.
- $\phi_n^{1/n} \rightarrow 1$.
- $\phi_n \leq 1, \forall n \in \mathbb{N}$.

From now on, for a regular sequence (θ_n) we will be referring to the limit $\theta = \lim \theta_n^{1/n}$ and the representation $\theta_n = \theta^n \phi_n$ as above.

The main theorem in this section is the following

Theorem 4.2 *Let $X = T(\theta_n, S_n)_\mathbb{N}$ be regular and let $\theta = \lim_n \theta_n^{1/n}$. Then*

- (1) *For all $Y \prec X$, $\ddot{\delta}_1(Y) = \theta$. Moreover for all $\varepsilon > 0$ there exists an equivalent norm $|\cdot|$ on X so that $\delta_1((X, |\cdot|), (e_i)) > \theta - \varepsilon$.*
- (2) *For all $Y \prec X$ and for all $n \in \mathbb{N}$, $\ddot{\delta}_n(Y) = \theta^n$ and $\ddot{\delta}_\omega(Y) = 0$.*
- (3) *For all $Y \prec X$, $I_\Delta(Y) = \begin{cases} \omega & \text{if } \theta = 1 \\ 1 & \text{if } \theta < 1 \end{cases}$*
- (4) *If $\frac{\theta_n}{\theta^n} \rightarrow 0$ then X is arbitrarily distortable.*

To prove the above theorem we need the following two results

Proposition 4.3 *Let $X = T(\theta_n, S_n)_\mathbb{N}$ be regular. Then for every $\varepsilon > 0$ there is an equivalent 1-unconditional norm $|\cdot|$ on X such that $\delta_1((X, |\cdot|), (e_i)) \geq \theta - \varepsilon$.*

Theorem 4.4 *Let $X = T(\theta_n, S_n)_\mathbb{N}$ be regular. Then for all $Y \prec X$ and $j \in \mathbb{N}$ we have*

$$\delta_j(Y) \leq \theta^j \sup_{p \geq j} \phi_p \vee \frac{\theta_j}{\theta_1}.$$

Proof of theorem 4.2

(1) To prove that if $Y \prec X$ then $\ddot{\delta}_1(Y) \leq \theta$ we note that if $\|\cdot\|$ is an equivalent norm on $T(\theta_i, S_i)_\mathbb{N}$ then there exists $C \geq 1$ such that $C^{-1}\delta_n(Y) \leq \delta_n(Y, \|\cdot\|) \leq C\delta_n(Y)$ for all $n \in \mathbb{N}$. Let $\delta_n \equiv \delta_n(Y, \|\cdot\|)$. Then since for all n and m , $\delta_{n+m} \geq \delta_n \delta_m$ we have $\lim_n \delta_n^{1/n} = \sup_n \delta_n^{1/n}$ exists. Hence $\delta_1 \leq \lim \delta_n^{1/n} = \lim \delta_n(Y)^{1/n}$, the latter limit existing for the same reason. Now

$$\lim \delta_n(Y)^{1/n} \leq \lim_{n \rightarrow \infty} (\theta^n \sup_{p \geq n} \phi_p \vee \frac{\theta_n}{\theta_1})^{1/n} = \theta$$

by theorem 4.4. Thus $\ddot{\delta}_1(Y) \leq \theta$ as was to be proved. The “moreover” part is proposition 4.3 and this completes the proof of $\ddot{\delta}_1(Y) = \theta$.

(2) Since $\ddot{\delta}_1(Y) = \theta$ we obtain $\ddot{\delta}_n(Y) = \theta^n$ from theorem 2.5. By theorem 4.4 we have that for all $\gamma \in \Delta(Y)$ and for all $j \in \mathbb{N}$,

$$\gamma_j \leq \theta^j \sup_{p \geq j} \phi_p \vee \frac{\theta_j}{\theta_1}.$$

Therefore, again by theorem 2.5, for all $\gamma \in \Delta(Y)$, $\gamma_\omega = \lim_{n \in \mathbb{N}} \gamma_n = 0$. Hence, for every equivalent norm $|\cdot|$ on Y , for every $\gamma \in \Delta(Y, |\cdot|)$, $\gamma_\omega = 0$. Since $\ddot{\delta}_\omega(Y) = \sup\{\gamma_\omega : \gamma \in \ddot{\Delta}(Y)\}$ we have $\ddot{\delta}_\omega(Y) = 0$.

(3) Follows immediately from (2)

(4) Let $\lambda > 1$. Choose $n \in \mathbf{N}$ so that $\sup_{p \geq n} \phi_p < \frac{\theta_1}{2\lambda}$. By (1) we can define an equivalent norm $\|\cdot\|$ on X such that

$$\delta_n((X, \|\cdot\|), (e_i)) \geq \delta_1((X, \|\cdot\|), (e_i))^n \geq \frac{\theta^n}{2}.$$

Let $Y \prec X$. By equation (2) of section 2, there exists $C > 0$ such that

$$C\|y\| \leq \|y\| \leq D(Y, \|\cdot\|)C\|y\|, \text{ for all } y \in Y.$$

Therefore by Observation 2.2,

$$D(Y, \|\cdot\|) \geq \frac{\delta_n(Y, \|\cdot\|)}{\delta_n(Y, \|\cdot\|)}.$$

Since $\delta_n(Y, \|\cdot\|) \geq \delta_n((X, \|\cdot\|), (e_i)) \geq \frac{\theta^n}{2}$, and $\delta_n(Y, \|\cdot\|) \leq \theta^n \sup_{p \geq n} \phi_p \vee \frac{\theta_n}{\theta_1} \leq \frac{1}{\theta_1} \theta^n \sup_{p \geq n} \phi_p$ (by theorem 4.4), we obtain $D(Y, \|\cdot\|) \geq \frac{\theta_1}{2 \sup_{p \geq n} \phi_p} > \lambda$. $\square$

The proof of proposition 4.3 comes from an argument in [OTW]. We recall this argument here.

Sketch of the proof of proposition 4.3 Fix $n \in \mathbf{N}$ such that $\theta_n^{1/n} > \theta - \varepsilon$ and set $a \equiv \theta_n^{1/n}$. For $j \in \mathbf{N}$ and $x \in X$ define

$$\begin{aligned} |x|_j &= \sup \left\{ a^j \sum_{i=1}^{\ell} \|E_i x\| : (E_i x)_1^{\ell} \text{ is } j\text{-admissible w.r.t. } (e_i) \right\} \text{ and} \\ |x| &= \frac{1}{n} \sum_{j=0}^{n-1} |x|_j \text{ (where } |\cdot|_0 = \|\cdot\|). \end{aligned}$$

We claim that $\delta_1((X, |\cdot|), (e_i)) \geq a$. To see this let $e_k \leq x_1 < x_2 < \dots < x_k$ in X and $x = \sum_{i=1}^k x_i$. For $j = 1, \dots, n-1$ we have $|x|_j \geq a \sum_{i=1}^k |x_i|_{j-1}$ (by the definitions of $|\cdot|_j$ and $|\cdot|_{j-1}$) and also $|x|_0 \geq a \sum_{i=1}^k |x_i|_{n-1}$ (since $a^n = \theta_n$). Therefore we get $|x| \geq a \sum_{i=1}^k |x_i|$. $\square$

To prove theorem 4.4 we need some norm estimates in $T(\theta_n, S_n)_{\mathbf{N}}$ for certain iterated rapidly increasing averages. Before defining what we mean by this we fix some terminology.

Let E be an interval in $\mathbf{N}$ and $x \in c_{00}$. We say that E *does not split* x if either $E \cap \text{ran}(x) = \emptyset$ or $\text{ran}(x) \subseteq E$. Let (x_i) be a block basis of (e_i) in c_{00} , $x \in \text{span}(x_i)_i$, $N \in \mathbf{N}$, and $E_1 < E_2 < \dots < E_N$ be intervals in $\mathbf{N}$ so that $\cup_{i=1}^N E_i \subseteq \text{ran}(x)$. We say that we *minimally shrink the intervals* $(E_{\ell})_{\ell=1}^N$ to obtain intervals $(F_{\ell})_{\ell=1}^N$ which don't split the x_i 's, if for $\ell = 1, \dots, N$ we let $G_{\ell} = E_{\ell} \setminus \cup \{\text{ran}(x_i) : E_{\ell} \text{ splits } x_i\}$ and let $F_1 < F_2 < \dots < F_N$ be the enumeration of the non-empty G_{ℓ} 's.

By a *tree* we shall mean a non-empty partially ordered set $(\mathcal{T}, \ll)$ for which the set $\{y \in \mathcal{T} : y \ll x\}$ is linearly ordered and finite for each $x \in \mathcal{T}$. If $\mathcal{T}' \subseteq \mathcal{T}$ then we say that $(\mathcal{T}', \ll)$ is a *subtree* of $(\mathcal{T}, \ll)$. The tree $\mathcal{T}$ is called *finite* if the set $\mathcal{T}$ is finite. The *initial* nodes of $\mathcal{T}$ are the minimal elements of $\mathcal{T}$ and the *terminal* nodes are the maximal elements. A *branch* in $\mathcal{T}$ is a maximal linearly ordered set in $\mathcal{T}$. The *immediate successors* of $x \in \mathcal{T}$ are all the nodes $y \in \mathcal{T}$ such that $x \ll y$ but there is no $z \in \mathcal{T}$ with $x \ll z \ll y$. If X is a linear space, then a *tree in* X is a tree whose nodes are vectors in X . If X is a Banach space with a basis (e_i) and $(x_i) \prec (e_i)$ then an *admissible averaging tree of* (x_i) , is a finite tree $\mathcal{T}$ in X with the following properties:

- $\mathcal{T} = (x_i^j)_{j=0, i=1}^{M, N^j}$ where $M \in \mathbf{N}$ and $1 = N^M \leq \dots \leq N^1 \leq N^0$.

- $x_1^j < \dots < x_{N^j}^j$ w.r.t. (e_s) ($j = 0, 1, \dots, M-1$) & $(x_i^0)_{i=1}^{N^0}$ is a subsequence of (x_s) .

Also for $j = 1, \dots, M$ and $i = 1, \dots, N^j$ we have the following:

- There exists a non-empty interval $I_i^j \subseteq \{1, \dots, N^{j-1}\}$ such that $\{x_s^{j-1} : s \in I_i^j\}$ are the immediate successors of x_i^j .
- $x_i^j = \frac{1}{|I_i^j|} \sum_{s \in I_i^j} x_s^{j-1}$.
- $(\min(\text{ran}(x_s^{j-1})))_{s \in I_i^j} \in S_1$ where $\text{ran}(x_s^{j-1})$ is taken w.r.t. (x_s) .

Note that the last two properties together require that x_i^j be a 1-admissible average of all of its immediate successors w.r.t. (x_s) . Let $\mathcal{T} = (x_i^j)_{j=0, i=1}^{M, N^j}$ be an admissible averaging tree as in the above definition, and let $b = \{y_M \ll \dots \ll y_0\}$ be a branch in $\mathcal{T}$. For $i = 0, 1, \dots, M$ we say that the *level* of y_i is i . Note that this is well defined, since the definition of admissible averaging trees forces every branch to have the same number of elements. Indeed for each i and j , the level of x_i^j in $\mathcal{T}$ is j . Let $\mathcal{T}$ be a tree, $x \in \mathcal{T}$ of level ℓ and $k \in \mathbb{N}$. By $\mathcal{T}(x, k)$ (resp. $\mathcal{T}^*(x, k)$) we shall denote the subtree of $\mathcal{T}' = \{x\} \cup \{y \in \mathcal{T} : y \gg x\}$ (resp. $\mathcal{T}' = \{y \in \mathcal{T} : y \gg x\}$) that contains all the nodes of $\mathcal{T}'$ that have level $\ell, \ell-1, \dots$, or $\ell-k+1$ in $\mathcal{T}$. Let $\mathcal{T}$ be an admissible averaging tree in a Banach space X with a basis (e_i) , $x \in \mathcal{T}$ with immediate successors $x_1 < \dots < x_n$ (a finite block basis of (e_i)), $k \in \mathbb{N}$, and let $F \subseteq \mathbb{N}$ be an interval which does not split any of $x_1, \dots, x_n$. Then by $\mathcal{T}_F(x, k)$ we shall denote the subtree of $\mathcal{T}(x, k)$ given by $\mathcal{T}_F(x, k) = \{x\} \cup \{y \in \mathcal{T}^*(x, k) : \text{ran}(y) \text{ (w.r.t. } (e_i)) \subseteq F\}$.

Definition 4.5 Let (x_i) be a block sequence of (e_i) in c_{00} , $M, N \in \mathbb{N}$, and let $(\varepsilon_i^j)_{j, i \in \mathbb{N}} \subset (0, 1)$. We say that x is an $(M, (\varepsilon_i^j), N)$ average of (x_i) w.r.t. (e_i) if there exists an admissible averaging tree $\mathcal{T} = (x_i^j)_{j=0, i=1}^{M, N^j}$ of (x_i) whose initial node is $x (= x_1^M)$ and

for $j = 1, \dots, M$ and $1 \leq i \leq N^j$ if $N_i^j = \max(\text{ran}(x_i^j))$ w.r.t. (e_s) ($N_0^j = N$), then x_i^j is an average of its immediate successors of length $k_i^j > \frac{2N_{i-1}^j}{\varepsilon_i^j}$.

$\mathcal{T}$ then will be called an $(M, (\varepsilon_i^j), N)$ admissible averaging tree of (x_i) w.r.t. (e_i) . For $i = 1, \dots, N^0$ set $N_i^0 = \max(\text{ran}(x_i^0))$ w.r.t. (e_s) , and $N_0^0 = N$. Then $(N_i^j)_{j=0, i=0}^{M, N^j}$ are called the maximum coordinates of $\mathcal{T}$ w.r.t. (e_i) .

Remark 4.6 Let X be a Banach space with basis (e_i) and let (x_i) be a block sequence of (e_i) with $\|x_i\| \leq 1$ for all $i \in \mathbb{N}$. Let $(\varepsilon_i^j)_{j, i \in \mathbb{N}} \subset (0, 1)$. Let $M, N \in \mathbb{N}$ and let x be an $(M, (\varepsilon_i^j), N)$ average of (x_i) w.r.t. (e_i) given by $\mathcal{T} = (x_i^j)_{j=0, i=1}^{M, N^j}$. Then we can write $x = \sum_{i \in F} a_i x_i$ for some finite set $F \subset \mathbb{N}$ such that

(1) $\sum_{i \in F} a_i = 1$ & $a_i > 0$ for all $i \in F$.

(2) x is M -admissible w.r.t. (x_i) (i.e. $F \in S_M$).

(3) Let $(N_i^j)_{j=0, i=0}^{M, N^j}$ be the maximum coordinates of $\mathcal{T}$ w.r.t. (e_s) . For $j = 1, \dots, M$ and $1 \leq i \leq N^j$, let $E_i^j(1) < E_i^j(2) < \dots < E_i^j(N_{i-1}^j)$ be a finite sequence of intervals in $\mathbb{N}$ with

$\cup_{\ell=1}^{N_{i-1}^j} E_i^j(\ell) \subseteq \text{ran}(x_i^j)$ and assume that we minimally shrink the $E_i^j(\ell)$'s to obtain intervals $(F_i^j(\ell))_{\ell=1}^{N_{i-1}^j}$ (some of which may be empty) which don't split the x_i^{j-1} 's. Then

$$\sum_{j=1}^M \sum_{i=1}^{N^j} \sum_{\ell=1}^{N_{i-1}^j} \|(E_i^j(\ell) \setminus F_i^j(\ell))x_i^j\| < \sum_{j,i} \varepsilon_i^j.$$

Indeed (1) and (2) are obvious. To see (3) note that for every $j = 1, \dots, M$, $1 \leq i \leq N^j$ and $\ell = 1, \dots, N_{i-1}^j$, the set $E_i^j(\ell)$ splits at most two x_s^{j-1} 's each of them having norm at most 1. Thus $\|(E_i^j(\ell) \setminus F_i^j(\ell))x_i^j\| \leq 2/k_i^j$ and so $\sum_{\ell=1}^{N_{i-1}^j} \|E_i^j(\ell) \setminus F_i^j(\ell)\| < 2N_{i-1}^j/k_i^j < \varepsilon_i^j$, which proves (3).

The concept of $(M, (\varepsilon_i^j), N)$ vectors is implicit in [AD] (see also [OTW]).

Proposition 4.7 *Let (x_i) be a block sequence in c_{00} , $M, N \in \mathbf{N}$ and $(\varepsilon_i^j)_{j,i \in \mathbf{N}} \subset (0, 1)$. Then there exists x which is an $(M, (\varepsilon_i^j), N)$ average of (x_i) w.r.t. (e_i) .*

Proof Note that by replacing each $(\varepsilon_i^j)_i$ by a smaller sequence if necessary we may assume that $(\varepsilon_i^j)_i$ is decreasing. For $M = 1$ we choose x_1^1 to be an average of $k_1^1 > 2N/\varepsilon_1^1$ many x_s 's chosen from $\{x_s : s \geq k_1^1\}$. Next, consider the case $M = 2$. At first we continue the argument that we gave for $M = 1$ to construct $\bar{x}_1^1 < \bar{x}_2^1 < \dots$ as follows: For $\bar{k}_1^1 > 2N/\varepsilon_1^1$ let $\bar{x}_1^1$ be an average of $\bar{k}_1^1$ many x_s 's chosen from $\{x_s : s \geq \bar{k}_1^1\}$. If $\bar{x}_i^1$ has been constructed for some $i \in \mathbf{N}$, and $\bar{k}_{i+1}^1 > 2\bar{N}_i^1/\varepsilon_{i+1}^1$, then $\bar{x}_{i+1}^1$ is taken to be an average of $\bar{k}_{i+1}^1$ many x_s 's chosen from $\{x_s : s \geq \bar{k}_{i+1}^1\}$ where $\bar{N}_i^1 = \max(\text{ran}(\bar{x}_i^1))$ w.r.t. (e_s) . Note that $\bar{x}_i^1 < \bar{x}_{i+1}^1$ since $\varepsilon_{i+1}^1 < 1$. Also note that for every $i \in \mathbf{N}$, $\bar{x}_i^1$ is a 1-admissible w.r.t. (x_s) . Then for $k_1^2 > 2N/\varepsilon_1^2$ take x_1^2 to be an average of k_1^2 many $\bar{x}_s^1$'s chosen from $\{\bar{x}_s^1 : \bar{x}_s^1 \geq x_{k_1^2}^2\}$. Then the $(2, (\varepsilon_i^j), N)$ admissible averaging tree $\mathcal{T}$ of (x_i) that corresponds to x_1^2 is determined as follows: $x_1^2 \in \mathcal{T}$. If $x_1^2 = \frac{1}{|F|} \sum_{i \in F} \bar{x}_i^1$ for some finite set $F \subset \mathbf{N}$ then $\bar{x}_i^1 \in \mathcal{T}$ for $i \in F$. For each $i \in F$ if $\bar{x}_i^1 = \frac{1}{|F_i|} \sum_{s \in F_i} x_s$ for some finite set $F_i \subset \mathbf{N}$ then $x_s \in \mathcal{T}$ for $s \in F_i$. Enumerate the x_s 's in $\mathcal{T}$ as $x_1^0 < x_2^0 < \dots < x_{N_0}^0$ and the $\bar{x}_s^1$'s in $\mathcal{T}$ as $x_1^1 < x_2^1 < \dots < x_{N_1}^1$. Since x_1^2 is a 1-admissible average of (x_i^1) w.r.t. (x_i) and for each $i = 1, \dots, N^1$, x_i^1 is 1-admissible w.r.t. (x_s) , we have that x_1^2 is 2-admissible w.r.t. (x_i) . We let the k_i^j 's and N_i^j 's be defined by definition 4.5. Each k_i^1 will be $\bar{k}_{i'}^1$ for some $i' \geq i$ and $N_0^1 = N$ while $N_i^1 = N_{i'}^1$. Since (ε_i^1) is decreasing the condition $k_i^1 > 2N_{i-1}^1/\varepsilon_i^1$ remains valid. The case $M > 2$ is proved by iterating this procedure. $\square$

Remark 4.8 *Definition 4.5 requires only that $k_i^j > 2N_{i-1}^j/\varepsilon_i^j$. The proof shows that we could also construct (x_i^j) so that $k_i^j > \frac{6(N_{i-1}^j)^2}{\theta_1 \varepsilon_i^j}$. We will use this remark in lemma 4.12.*

Next we prove some norm estimates for $(M, (\varepsilon_i^j), N)$ averages in $T(\theta_n, S_n)_{\mathbf{N}}$. $\|\cdot\|$ will always denote the norm of $T(\theta_n, S_n)_{\mathbf{N}}$. We need for $p \in \mathbf{N} \cup \{0\}$ and $N \in \mathbf{N}$ to define the equivalent norms $\|\cdot\|_p$ and $\|\cdot\|_{S_N, p}$ and the continuous seminorms $\|\cdot\|_{N, p}$ as follows ($\|\cdot\|_0 = \|\cdot\|$ and $\theta_0 = 1$):

$$\begin{aligned} \|x\|_p &= \theta_p \sup \left\{ \sum \|E_i x\| : (E_i) \text{ is a } p\text{-admissible sequence of intervals} \right\} \\ \|x\|_{N, p} &= \sup \left\{ \sum_1^N \|E_i x\|_p : N \leq E_1 < E_2 < \dots < E_N \text{ are intervals} \right\} \text{ and} \\ \|x\|_{S_N, p} &= \sup \left\{ \sum \|E_i x\|_p : (E_i) \text{ is an } N\text{-admissible sequence of intervals} \right\}. \end{aligned}$$

Of course for $x \in c_{00}$ each “sup” above is a “max” and there exists $p \in \mathbb{N}$ so that $\|x\| = \|x\|_p$ if $\|x\| \neq \|x\|_\infty$.

Remark 4.9 Let $\theta_0 = 1$. For all $x \in c_{00}$ and for all $p \in \mathbb{N}$ we have

$$\|x\|_p \leq \frac{\theta_p}{\theta_{p-1}} \|x\|_{S_{1,p-1}}.$$

Moreover if $p = 1$ we have equality.

Indeed there exists $(E_i)_{i \in I}$ a p -admissible family of intervals such that

$$\|x\|_p = \theta_p \sum_{i \in I} \|E_i x\|.$$

We can write $I = \cup_1^\ell I_j$ where $(E_i)_{i \in I_j}$ is $p-1$ -admissible and if F_j is the smallest interval including $\cup_{i \in I_j} E_i$ then $(F_j)_{j=1}^\ell$ is 1-admissible. Thus

$$\|x\|_p = \frac{\theta_p}{\theta_{p-1}} \sum_{j=1}^\ell \theta_{p-1} \sum_{i \in I_j} \|E_i x\| \leq \frac{\theta_p}{\theta_{p-1}} \sum_{j=1}^\ell \|F_j x\|_{p-1} \leq \frac{\theta_p}{\theta_{p-1}} \|x\|_{S_{1,p-1}}. \quad \square$$

Notation If $A \subset [0, \infty)$ is a finite non-empty set, we set $A^* = A \setminus \{\max(A)\}$.

Observation 4.10 Let $N \in \mathbb{N}$ and $D, \varepsilon > 0$. Note that if $k \geq \frac{ND}{\varepsilon}$ and $A_\ell \subset [0, D]$ for $\ell = 1, \dots, N$ are finite sets with $|A_1| + \dots + |A_N| \leq k$ then $\frac{1}{k} \sum_{\ell=1}^N \sum \{a : a \in A_\ell\} \leq \max(\cup_{\ell=1}^N A_\ell^*) + \varepsilon$.

We will apply this for $D = \frac{1}{\theta_1}$ in the proof of (2) of lemma 4.11 below.

Lemma 4.11 Let non-zero vectors $k \leq x_1 < x_2 < \dots < x_k$ with $\|x_i\| \leq 1$ for all i , $x = \frac{1}{k}(x_1 + \dots + x_k)$ and $\varepsilon \in (0, 1)$. Let $F \subseteq \text{ran}(x)$ be an interval in $\mathbb{N}$ which does not split the x_i 's. Set $\theta_0 = 1$, $N_i = \max(\text{ran}(x_i))$ w.r.t. (e_j) , $N_0 = 1$ and let $N \in \mathbb{N}$. If $k > \frac{6N}{\theta_1 \varepsilon}$ then

- (1) For every $p \in \mathbb{N}$, $\|Fx\|_{N,p} \leq \frac{\theta_p}{\theta_{p-1}} \max\{\|x_i\|_{N_{i-1},p-1} : \text{ran}(x_i) \subseteq F\} + \varepsilon$.
- (2) There exists $n \in \mathbb{N}$, intervals $F_1 < F_2 < \dots < F_n$ which don't split any x_i , $\cup_{\ell=1}^n F_\ell \subseteq \text{ran}(x)$, and $(p_\ell)_{\ell=1}^n \subset \mathbb{N}$ so that

$$\|x\|_{N,0} \leq \max \left(\bigcup_{\ell=1}^n \left\{ \frac{\theta_{p_\ell}}{\theta_{p_\ell-1}} \|x_i\|_{N_{i-1},p_\ell-1} : \text{ran}(x_i) \subset F_\ell \right\}^* \right) + \varepsilon.$$

Proof (1) For $p \in \mathbb{N}$ there exist intervals $N \leq E_1 < \dots < E_N$ such that $\cup_{\ell=1}^N E_\ell \subseteq F$ and

$$\|Fx\|_{N,p} = \sum_{\ell=1}^N \|E_\ell x\|_p \leq \frac{\theta_p}{\theta_{p-1}} \sum_{\ell=1}^N \|E_\ell x\|_{S_{1,p-1}} \text{ (by Remark 4.9) }.$$

We minimally shrink the intervals $(E_i)_1^N$ to get $n \leq N$ and intervals $N \leq F_1 < F_2 < \dots < F_n$ which don't split the x_i 's. Since each E_ℓ splits at most two x_i 's, $\|\cdot\|_{S_{1,p-1}} \leq \frac{1}{\theta_1} \|\cdot\|$ and $\frac{\theta_p}{\theta_{p-1}} \leq 1$,

$$\frac{\theta_p}{\theta_{p-1}} \sum_{\ell=1}^N \|E_\ell x\|_{S_{1,p-1}} \leq \frac{\theta_p}{\theta_{p-1}} \sum_{\ell=1}^n \|F_\ell x\|_{S_{1,p-1}} + \frac{2N}{k\theta_1}.$$

Fix an $\ell \in \{1, \dots, n\}$. There exists a 1-admissible family of intervals $(F_{\ell,m})_m$ with $F_{\ell,m} \subseteq F_\ell$ for all m and $\|F_\ell x\|_{s_1,p-1} = \sum_m \|F_{\ell,m} x\|_{p-1}$. Let s be minimal with $\text{ran}(x_s) \cap F_{\ell,1} \neq \emptyset$ (we may assume that such an s exists) and t be maximal with $\text{ran}(x_t) \cap F_\ell \neq \emptyset$. Then

$$\begin{aligned} \sum_m \|F_{\ell,m} x\|_{p-1} &\leq \frac{1}{k} (\sum_m \|F_{\ell,m} x_s\| + \|x_{s+1}\|_{N_s,p-1} + \dots + \|x_t\|_{N_s,p-1}) \\ &\leq \frac{1}{k} \left(\frac{1}{\theta_1} + \sum_{i=s+1}^t \|x_i\|_{N_{i-1},p-1} \right). \end{aligned}$$

Set $[r, R] \equiv \{i : \text{ran}(x_i) \subseteq F\}$. Hence

$$\frac{\theta_p}{\theta_{p-1}} \sum_{\ell=1}^n \|F_\ell x\|_{s_1,p-1} \leq \frac{\theta_p}{\theta_{p-1}} \frac{1}{k} \left(\frac{n}{\theta_1} + \|x_{r+1}\|_{N_r,p-1} + \|x_{r+2}\|_{N_{r+1},p-1} + \dots + \|x_R\|_{N_{R-1},p-1} \right).$$

Therefore we have proved that

$$\|Fx\|_{N,p} \leq \frac{1}{k} \frac{\theta_p}{\theta_{p-1}} \left(\|x_{r+1}\|_{N_r,p-1} + \|x_{r+2}\|_{N_{r+1},p-1} + \dots + \|x_R\|_{N_{R-1},p-1} \right) + \frac{3N}{k\theta_1}.$$

Thus

$$\|Fx\|_{N,p} \leq \frac{1}{k} \frac{\theta_p}{\theta_{p-1}} \sum \{ \|x_i\|_{N_{i-1},p-1} : \text{ran}(x_i) \subseteq F \} + \frac{3N}{k\theta_1}. \quad (3)$$

This yields (1).

(2) Choose intervals $N \leq E_1 < E_2 < \dots < E_N$ such that $\|x\|_{N,0} = \sum_{\ell=1}^N \|E_\ell x\|$. As before, we minimally shrink the intervals (E_i) to obtain $n \leq N$ and non-empty intervals $F_1 < F_2 < \dots < F_n$ which don't split the x_i 's and satisfy

$$\sum_{\ell=1}^N \|E_\ell x\| \leq \sum_{\ell=1}^n \|F_\ell x\| + \frac{2N}{k}.$$

Fix $\ell \in \{1, \dots, n\}$. If $\|F_\ell x\| \neq \|F_\ell x\|_\infty$ there exists $p_\ell \in \mathbb{N}$ such that $\|F_\ell x\| = \|F_\ell x\|_{p_\ell}$. By equation (3) for $N = 1$ we get

$$\|F_\ell x\|_{p_\ell} \leq \frac{1}{k} \frac{\theta_{p_\ell}}{\theta_{p_\ell-1}} \left(\sum \{ \|x_i\|_{N_{i-1},p_\ell-1} : \text{ran}(x_i) \subseteq F_\ell \} \right) + \frac{3}{k\theta_1}. \quad (4)$$

If $\|F_\ell x\| = \|F_\ell x\|_\infty$ then $\|F_\ell x\| \leq \frac{1}{k}$ and so (4) still is valid. Thus

$$\begin{aligned} \|x\|_{N,0} &\leq \frac{1}{k} \sum_{\ell=1}^n \frac{\theta_{p_\ell}}{\theta_{p_\ell-1}} \sum \{ \|x_i\|_{N_{i-1},p_\ell-1} : \text{ran}(x_i) \subseteq F_\ell \} + \frac{5N}{k\theta_1} \\ &< \max \left(\bigcup_{\ell=1}^n \left\{ \frac{\theta_{p_\ell}}{\theta_{p_\ell-1}} \|x_i\|_{N_{i-1},p_\ell-1} : \text{ran}(x_i) \subset F_\ell \right\}^* \right) + \varepsilon \end{aligned}$$

by observation 4.10 since $\|\cdot\|_{N_{i-1},p_\ell-1} \leq \frac{1}{\theta_1} \|\cdot\|$, and $k > \frac{6N}{\varepsilon\theta_1} = \frac{N}{(\varepsilon/6)\theta_1}$. $\square$

Combining lemma 4.11 with proposition 4.7 and remark 4.8 we obtain

Lemma 4.12 Let (x_i) be a normalized block sequence in $X = T(\theta_i, S_i)_{\mathbf{N}}$, $M, N \in \mathbf{N}$ and $(\varepsilon_i^j)_{j,i \in \mathbf{N}} \subset (0, 1)$. There exists x , an $(M, (\varepsilon_i^j), N)$ average of (x_i) w.r.t. (e_i) , so that if $\mathcal{T} = (x_i^j)_{j=0, i=1}^{M, N^j}$ is the $(M, (\varepsilon_i^j), N)$ admissible averaging tree of (x_i) with $x = x_1^M$, and $(N_i^j)_{j=0, i=0}^{M, N^j}$ are the maximum coordinates of $\mathcal{T}$ w.r.t. (e_i) then for $j = 1, \dots, M$ and $i = 1, \dots, N^j$ we have the following properties:

(1) For every $p \in \mathbf{N}$ and every $F \subseteq \text{ran}(x_i^j)$ which does not split any x_s^{j-1} we have

$$\|Fx_i^j\|_{N_{i-1, p}^j} \leq \frac{\theta_p}{\theta_{p-1}} \max\{\|x_s^{j-1}\|_{N_{s-1, p-1}^{j-1}} : \text{ran}(x_s^{j-1}) \subseteq F\} + \varepsilon_i^j / N_{i-1}^j.$$

(2) There exists $n \in \mathbf{N}$ and intervals $F_1 < F_2 < \dots < F_n$ which don't split any x_s^{j-1} , $(\bigcup_{\ell=1}^n F_\ell \subseteq \text{ran}(x_i^j))$ and $(p_\ell)_{\ell=1}^n \subseteq \mathbf{N}$ such that

$$\|x_i^j\|_{N_{i-1, 0}^j} \leq \max\left(\bigcup_{\ell=1}^n \left\{\frac{\theta_{p_\ell}}{\theta_{p_\ell-1}} \|x_s^{j-1}\|_{N_{s-1, p_\ell-1}^{j-1}} : \text{ran}(x_s^{j-1}) \subseteq F_\ell\right\}^*\right) + \varepsilon_i^j.$$

Lemma 4.13 Let (x_i) be a normalized block sequence in $X = T(\theta_i, S_i)_{\mathbf{N}}$, $\varepsilon > 0$, $(\varepsilon_i^j)_{j,i \in \mathbf{N}} \subset (0, 1)$ with $\sum_{j,i} \varepsilon_i^j < \varepsilon$ and let x be an $(M, (\varepsilon_i^j), N)$ average of (x_i) w.r.t. (e_i) . Let $\mathcal{T} = (x_i^j)_{j=0, i=1}^{M, N^j}$ be the $(M, (\varepsilon_i^j), N)$ admissible averaging tree of (x_i) with $x = x_1^M$, let $(N_i^j)_{j=0, i=0}^{M, N^j}$ be the maximum coordinates of $\mathcal{T}$ w.r.t. (e_i) and assume that for $j = 1, \dots, M$ and $i = 1, \dots, N^j$ the properties (1) and (2) of lemma 4.12 are satisfied. Then we have

(3) If $0 \leq p' < p$, $p - p' \leq j \leq M$, $1 \leq i \leq N^j$ and $F \subseteq \text{ran}(x_i^j)$ is an interval which does not split any x_s^{j-1} then

$$\|Fx_i^j\|_{N_{i-1, p}^j} \leq \frac{\theta_p}{\theta_{p'}} \max\{\|x_s^{j-(p-p')}\|_{N_{s-1}^{j-(p-p'), p'}} : \text{ran}(x_s^{j-(p-p')}) \subseteq F\} + \sum_{x_s^k \in \mathcal{T}_F(x_i^j, p-p')} \frac{\varepsilon_s^k}{N_{s-1}^k}.$$

(4) If $1 \leq p \leq j \leq M$, $1 \leq i \leq N^j$ and $F \subseteq \mathbf{N}$ is an interval which does not split any x_s^{j-1} then

$$\|Fx_i^j\|_{N_{i-1, p}^j} \leq \theta_p \max\{\|x_s^{j-p}\|_{N_{s-1}^{j-p, 0}} : \text{ran}(x_s^{j-p}) \subseteq F\} + \sum \left\{ \frac{\varepsilon_s^k}{N_{s-1}^k} : x_s^k \in \mathcal{T}_F(x_i^j, p) \right\}.$$

(5) There exists $m \in \mathbf{N}$ and intervals $F_1 < F_2 < \dots < F_m$ ($\bigcup_\ell F_\ell \subseteq \text{ran}(x_1^M)$) which don't split the x_s^0 's and $(p_\ell)_{\ell=1}^m \subset \mathbf{N}$ with $p_\ell \geq M$ for all ℓ , such that

$$\|x_1^M\| \leq \max\left(\bigcup_{\ell=1}^m \left\{ \frac{\theta_{p_\ell}}{\theta_{p_\ell-M}} \|x_s^0\|_{N_{s-1}^0, p_\ell-M} : \text{ran}(x_s^0) \subseteq F_\ell \right\}^*\right) + \varepsilon.$$

Proof

(3) By (1) of lemma 4.12 we have

$$\|Fx_i^j\|_{N_{i-1, p}^j} \leq \frac{\theta_p}{\theta_{p-1}} \max\{\|x_s^{j-1}\|_{N_{s-1, p-1}^{j-1}} : \text{ran}(x_s^{j-1}) \subseteq F\} + \frac{\varepsilon_i^j}{N_{i-1}^j}$$

$$\begin{aligned}
&\leq \frac{\theta_p}{\theta_{p-1}} \frac{\theta_{p-1}}{\theta_{p-2}} \max\{\|x_s^{j-2}\|_{N_{s-1}^{j-2}, p-2} : \text{ran}(x_s^{j-2}) \subseteq F\} + \sum\{\frac{\varepsilon_s^k}{N_{s-1}^k} : x_s^k \in \mathcal{T}_F(x_i^j, 2)\} \\
&\leq \dots \\
&\leq \frac{\theta_p}{\theta_{p-1}} \frac{\theta_{p-1}}{\theta_{p-2}} \dots \frac{\theta_{p'+1}}{\theta_{p'}} \max\{\|x_s^{j-(p-p')}\|_{N_{s-1}^{j-(p-p')}, p'} : \\
&\quad \text{ran}(x_s^{j-(p-p')}) \subseteq F\} + \sum\{\frac{\varepsilon_s^k}{N_{s-1}^k} : x_s^k \in \mathcal{T}_F(x_i^j, p-p')\}.
\end{aligned}$$

(4) Follows immediately from (3), letting $p' = 0$.

(5) We prove by induction on J that

for $J = 1, \dots, M$ and $1 \leq i \leq N^J$ there exists $m \in \mathbf{N}$, intervals $F_1 < F_2 < \dots < F_m$ ($\cup_\ell F_\ell \subseteq \text{ran}(x_i^J)$) that don't split the x_s^0 's, and $(p_\ell)_{\ell=1}^m \subset \mathbf{N}$ with $p_\ell \geq J$ for all ℓ , such that

$$\|x_i^J\|_{N_{i-1}^J, 0} \leq \max\left(\bigcup_{\ell=1}^m \left\{\frac{\theta_{p_\ell}}{\theta_{p_\ell-J}} \|x_s^0\|_{N_{s-1}^0, p_\ell-J} : \text{ran}(x_s^0) \subseteq F_\ell\right\}^*\right) + \sum\{\varepsilon_s^k : x_s^k \in \mathcal{T}(x_i^J, J)\}$$

((5) then follows by taking $(J, i) = (M, 1)$ and noting that $\|x_1^M\| \leq \|x_1^M\|_{N,0} = \|x\|_{N_0^M,0}$. Indeed, for $J = 1$ this follows from the statement of (2) for $j = 1$. Assume that the statement is proved for all positive integers $\leq J$ where $J \leq M - 1$. By (2) there exist intervals $F'_1 < \dots < F'_n$ ($\cup_\ell F'_\ell \subseteq \text{ran}(x_i^{J+1})$) which don't split the x_s^J 's, and $(p'_\ell)_{\ell=1}^n$ such that

$$\|x_i^{J+1}\|_{N_{i-1}^{J+1}, 0} \leq \max\left(\bigcup_{\ell=1}^n \left\{\frac{\theta_{p'_\ell}}{\theta_{p'_\ell-1}} \|x_s^J\|_{N_{s-1}^J, p'_\ell-1} : \text{ran}(x_s^J) \subseteq F'_\ell\right\}^*\right) + \varepsilon_i^{J+1}.$$

If $p'_\ell - 1 = 0$ for some ℓ and $\text{ran}(x_s^J) \subseteq F'_\ell$ then by the induction hypothesis there exists $M(s) \in \mathbf{N}$, intervals $F_1(s) < F_2(s) < \dots < F_{M(s)}(s)$ ($\cup_\mu F_\mu(s) \subseteq \text{ran}(x_s^J)$) that don't split the x_t^0 's and $(p_\mu(s))_{\mu=1}^{M(s)} \subset \mathbf{N}$ with $p_\mu(s) \geq J$ for all μ such that

$$\|x_s^J\|_{N_{s-1}^J, 0} \leq \max\left(\bigcup_{\mu=1}^{M(s)} \left\{\frac{\theta_{p_\mu(s)}}{\theta_{p_\mu(s)-J}} \|x_t^0\|_{N_{t-1}^0, p_\mu(s)-J} : \text{ran}(x_t^0) \subseteq F_\mu(s)\right\}^*\right) + \sum\{\varepsilon_t^k : x_t^k \in \mathcal{T}(x_s^J, J)\}.$$

If $0 < p'_\ell - 1 \leq J$ for some ℓ , and $\text{ran}(x_s^J) \subseteq F'_\ell$ then by (4),

$$\|x_s^J\|_{N_{s-1}^J, p'_\ell-1} \leq \theta_{p'_\ell-1} \max\{\|x_t^{J-p'_\ell+1}\|_{N_{t-1}^{J-p'_\ell+1}, 0} : \text{ran}(x_t^{J-p'_\ell+1}) \subseteq \text{ran}(x_s^J)\} + \sum_{x_t^k \in \mathcal{T}(x_s^J, p'_\ell-1)} \varepsilon_t^k.$$

For the remaining ℓ 's we have by (3) for $j = J$, $p = p'_\ell - 1$ and $p' = p'_\ell - 1 - J$,

$$\|x_s^J\|_{N_{s-1}^J, p'_\ell-1} \leq \frac{\theta_{p'_\ell-1}}{\theta_{p'_\ell-1-J}} \max\{\|x_t^0\|_{N_{t-1}^0, p'_\ell-1-J} : \text{ran}(x_t^0) \subseteq \text{ran}(x_s^J)\} + \sum\{\varepsilon_t^k : x_t^k \in \mathcal{T}(x_s^J, J)\}.$$

Combining these estimates we get

$$\|x_i^{J+1}\|_{N_{i-1}^{J+1}, 0} \leq$$

$$\begin{aligned}
& \max \left(\bigcup_{\{\ell: p'_\ell=1\}} \bigcup_{\{s: \text{ran}(x_s^J) \subseteq F'_\ell\}} \bigcup_{\mu=1}^{M(s)} \left\{ \frac{\theta_1 \theta_{p_\mu(s)}}{\theta_{p_\mu(s)-J}} \|x_t^0\|_{N_{t-1}^0, p_\mu(s)-J} + \sum \{\varepsilon_w^k : x_w^k \in \mathcal{T}(x_s^J, J)\} : \text{ran}(x_t^0) \subseteq F_\mu(s) \right\}^* \right. \\
& \cup \bigcup_{\{\ell: 0 < p'_\ell-1 \leq J\}} \left\{ \theta_{p'_\ell} \|x_t^{J-p'_\ell+1}\|_{N_{t-1}^{J-p'_\ell+1}, 0} + \sum \{\varepsilon_s^k : x_s^k \in \mathcal{T}^*(x_i^{J+1}, p'_\ell)\} : \text{ran}(x_t^{J-p'_\ell+1}) \subseteq F'_\ell \right\}^* \\
& \left. \cup \bigcup_{\{\ell: p'_\ell > J+1\}} \left\{ \frac{\theta_{p'_\ell}}{\theta_{p'_\ell-(J+1)}} \|x_t^0\|_{N_{t-1}^0, p'_\ell-(J+1)} + \sum \{\varepsilon_s^k : x_s^k \in \mathcal{T}^*(x_i^{J+1}, J+1)\} : \text{ran}(x_t^0) \subseteq F'_\ell \right\}^* \right) + \varepsilon_i^{J+1}.
\end{aligned}$$

The induction hypothesis gives that for $0 < p'_\ell-1 < J$ and $1 \leq t \leq N^{J-p'_\ell+1}$ with $\text{ran}(x_t^{J-p'_\ell+1}) \subseteq F'_\ell$, there exists $K(\ell, t) \in \mathbb{N}$ and sets $G_1(\ell, t) < G_2(\ell, t) < \dots < G_{K(\ell, t)}(\ell, t)$ which don't split the x_s^0 's such that $\cup_k G_k(\ell, t) \subseteq \text{ran}(x_t^{J-p'_\ell+1})$, and there exist $(q_k(\ell, t))_{k=1}^{K(\ell, t)} \subset \mathbb{N}$ with $q_k(\ell, t) \geq J - p'_\ell + 1$ such that

$$\begin{aligned}
\|x_t^{J-p'_\ell+1}\|_{N_{t-1}^{J-p'_\ell+1}, 0} & \leq \max \left(\bigcup_{k=1}^{K(\ell, t)} \left\{ \frac{\theta_{q_k(\ell, t)}}{\theta_{q_k(\ell, t)-(J-p'_\ell+1)}} \|x_s^0\|_{N_{s-1}^0, q_k(\ell, t)-(J-p'_\ell+1)} : \text{ran}(x_s^0) \subseteq G_k(\ell, t) \right\}^* \right) \\
& + \sum \{\varepsilon_s^k : x_s^k \in \mathcal{S}(\ell, t)\}
\end{aligned}$$

where $\mathcal{S}(\ell, t) = \mathcal{T}(x_t^{J-p'_\ell+1}, J - p_\ell + 1)$. Thus, these estimates give

$$\begin{aligned}
& \|x_i^{J+1}\|_{N_{i-1}^{J+1}, 0} \leq \\
& \max \left(\bigcup_{\{\ell: p'_\ell=1\}} \bigcup_{\{s: \text{ran}(x_s^J) \subseteq F'_\ell\}} \bigcup_{\mu=1}^{M(s)} \left\{ \frac{\theta_1 \theta_{p_\mu(s)}}{\theta_{(1+p_\mu(s))-(J+1)}} \|x_t^0\|_{N_{t-1}^0, p_\mu(s)-J} \right. \right. \\
& \quad \left. \left. + \sum \{\varepsilon_w^k : x_w^k \in \mathcal{T}(x_s^J, J)\} : \text{ran}(x_t^0) \subseteq F_\mu(s) \right\}^* \right. \\
& \cup \bigcup_{\{\ell: 0 < p'_\ell-1 < J\}} \bigcup_{k=1}^{K(\ell, t)} \left\{ \frac{\theta_{p'_\ell} \theta_{q_k(\ell, t)}}{\theta_{(p'_\ell+q_k(\ell, t))-(J+1)}} \|x_s^0\|_{N_{s-1}^0, q_k(\ell, t)-(J-p'_\ell+1)} \right. \\
& \quad \left. + \sum \{\varepsilon_s^k : x_s^k \in \mathcal{T}^*(x_i^{J+1}, p'_\ell) \cup \mathcal{S}(\ell, t)\} : \text{ran}(x_s^0) \subseteq G_k(\ell, t) \right\}^* \\
& \cup \bigcup_{\{\ell: p'_\ell=J+1\}} \left\{ \theta_{J+1} \|x_t^0\|_{N_{t-1}^0, 0} + \sum \{\varepsilon_s^k : x_s^k \in \mathcal{T}^*(x_i^{J+1}, J+1)\} : \text{ran}(x_t^0) \subseteq F'_\ell \right\}^* \\
& \left. \cup \bigcup_{\{\ell: p'_\ell > J+1\}} \left\{ \frac{\theta_{p'_\ell}}{\theta_{p'_\ell-(J+1)}} \|x_t^0\|_{N_{t-1}^0, p'_\ell-(J+1)} + \sum \{\varepsilon_s^k : x_s^k \in \mathcal{T}^*(x_i^{J+1}, J+1)\} : \text{ran}(x_t^0) \subseteq F'_\ell \right\}^* \right) + \varepsilon_i^{J+1}.
\end{aligned}$$

Note that $\theta_1 \theta_{p_\mu(s)} \leq \theta_{1+p_\mu(s)}$, $1+p_\mu(s) \geq J+1$, $\theta_{p'_\ell} \theta_{q_k(\ell, t)} \leq \theta_{p'_\ell+q_k(\ell, t)}$, $p'_\ell+q_k(\ell, t) \geq p'_\ell+(J-p'_\ell+1) = J+1$, the sets $F_\mu(s)$'s F'_ℓ 's and $G_k(\ell, t)$'s don't split the x_s^0 's, and arranged in successive order, give the required sequence $F_1 < \dots < F_m$. Then $1+p_\mu(s)$'s, $p'_\ell+q_k(\ell, t)$'s, and p'_ℓ 's for $p'_\ell \geq J+1$ arranged in the corresponding order, give the required sequence $(p_\ell)_{\ell=1}^m$. This finishes the induction. $\square$

Combining lemmas 4.12 and 4.13 we immediately obtain

Corollary 4.14 *Let (x_i) be a normalized block sequence in $X = T(\theta_i, S_i)_{\mathbf{N}}$, $M, N \in \mathbf{N}$, $\varepsilon > 0$ and $(\varepsilon_i^j)_{j,i \in \mathbf{N}} \subset (0, 1)$ with $\sum_{j,i} \varepsilon_i^j < \varepsilon$. There exists x an $(M, (\varepsilon_i^j), N)$ average of (x_i^0) w.r.t. (e_i) , so that if $\mathcal{T} = (x_i^j)_{j=0,i=1}^{M,N^j}$ is the admissible averaging tree of (x_i) with $x = x_1^M$, and $(N_i^j)_{j=0,i=0}^{M,N^j}$ are the maximum coordinates of $\mathcal{T}$ w.r.t. (e_i) , then*

- (1) *For $j = 1, \dots, M$, $i = 1, \dots, N^j$, $1 \leq p \leq j$ and an interval $F \subseteq \text{ran}(x_i^j)$ which does not split any x_s^{j-1} ,*

$$\|Fx_i^j\|_{N_{i-1}^{j-1},p} \leq \theta_p \max\{\|x_s^{j-p}\|_{N_{s-1}^{j-p},0} : \text{ran}(x_s^{j-p}) \subseteq F\} + \sum\{\frac{\varepsilon_s^k}{N_{s-1}^k} : x_s^k \in \mathcal{T}_F(x_i^j, p)\}.$$

- (2) *There exists $m \in \mathbf{N}$ and intervals $F_1 < F_2 < \dots < F_m$ which don't split the x_s^0 's and $(p_\ell)_{\ell=1}^m \subset \mathbf{N}$ with $p_\ell \geq M$ for all ℓ , such that*

$$\|x_1^M\| \leq \max\left(\bigcup_{\ell=1}^m \left\{\frac{\theta_{p_\ell}}{\theta_{p_\ell-M}} \|x_s^0\|_{N_{s-1}^0, p_\ell-M} : \text{ran}(x_s^0) \subseteq F_\ell\right\}^*\right) + \varepsilon.$$

To prove theorem 4.4 we need also the following

Lemma 4.15 *For all $J, N \in \mathbf{N}$, $\varepsilon > 0$ and $Y \prec X = T(\theta_i, S_i)_{\mathbf{N}}$ there exists $y \in Y$ with $\|y\| = 1$ and*

$$\|y\|_{N,p} < \phi_p(1 + \varepsilon), \text{ for all } p = 1, \dots, J.$$

Proof If this were false, then $\exists J, N \in \mathbf{N} \exists \varepsilon \in (0, 1/2) \exists Y \prec X$ such that

$$\|y\| \leq \max_{1 \leq p \leq J} \frac{1}{\phi_p(1 + \varepsilon)} \|y\|_{N,p} \text{ for all } y \in Y. \quad (5)$$

Since $(1 + \varepsilon)^n \phi_{J(n+1)} \rightarrow \infty$ as $n \rightarrow \infty$ we may choose $n \in \mathbf{N}$ such that

$$1 > \frac{1}{(1 + \varepsilon)^n \theta^J \theta_1 \phi_{J(n+1)}} + 2\varepsilon.$$

Let (x_s) be a normalized block sequence in Y and apply corollary 4.14 to (x_s) for $(M, \varepsilon, N) = (J(n+1), \varepsilon \theta_{J(n+1)} \phi_1^J, N)$ for an appropriate sequence (ε_i^j) , to construct $x = \sum a_s x_s^0$, a $(J(n+1), (\varepsilon_i^j), N)$ average of (x_s) w.r.t. (e_s) . Let x have a corresponding admissible averaging tree $\mathcal{T} = (x_i^j)_{j=0,i=1}^{J(n+1),N^j}$, and let the maximum coordinates of $\mathcal{T}$ be $(N_i^j)_{j=0,i=0}^{J(n+1),N^j}$ w.r.t. (e_i) . Define $\delta_i^j = \varepsilon_i^j / \phi_1^J$ for $j, i \in \mathbf{N}$ and note that $\sum \delta_i^j < \varepsilon \theta_{J(n+1)}$. Note that if $1 \leq p \leq J$ then $\phi_p \geq \phi_1^p \geq \phi_1^J$ and if $k, s \in \mathbf{N}$ then we have that $\frac{\varepsilon_s^k}{\phi_p} \leq \delta_s^k$. There exists $1 \leq p^1 \leq J$ so that

$$\theta_{J(n+1)} = \theta_{J(n+1)} \sum \|a_s x_s^0\| \leq \|x\| \leq \frac{1}{\phi_{p^1}(1 + \varepsilon)} \|x\|_{N,p^1} = \frac{1}{\phi_{p^1}(1 + \varepsilon)} \|x_1^{J(n+1)}\|_{N_0^{J(n+1)},p^1}$$

(since $N = N_0^{J(n+1)}$). Then by corollary 4.14 (1), there exists $s^1 \in \mathbf{N}$ so that $\text{ran}(x_{s^1}^{J(n+1)-p^1}) \subseteq \text{ran}(x_1^{J(n+1)})$ and also there exists a family of intervals $(E_i)_{i=1, \dots, N_{s^1-1}^{J(n+1)-p^1}} \subseteq \text{ran}(x_1^{J(n+1)})$ so that

$$\begin{aligned} \theta_{J(n+1)} &\leq \frac{1}{\phi_{p^1}(1 + \varepsilon)} \left(\theta_{p^1} \|x_{s^1}^{J(n+1)-p^1}\|_{N_{s^1-1}^{J(n+1)-p^1},0} + \sum\{\varepsilon_s^k : x_s^k \in \mathcal{T}(x_1^{J(n+1)}, p^1)\} \right) \\ &\leq \sum_{i=1}^{N_{s^1-1}^{J(n+1)-p^1}} \frac{\theta_{p^1}}{1 + \varepsilon} \|E_i x_{s^1}^{J(n+1)-p^1}\| + \sum\{\delta_s^k : x_s^k \in \mathcal{T}(x_1^{J(n+1)}, p^1)\} \end{aligned}$$

We minimally shrink the E_i 's if necessary, to obtain (F_i) which don't split the $x_s^{J(n+1)-p^1-1}$'s. Let $\mathcal{A}$ be the set of $x_s^{J(n+1)-p^1-1}$'s that is split by the E_i 's. Thus we get

$$\theta_{J(n+1)} \leq \sum_i \frac{\theta^{p^1}}{1+\varepsilon} \|F_i x_{s^1}^{J(n+1)-p^1}\| + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{T}(x_1^{J(n+1)}, p^1)\}.$$

Similarly by 5 for each i there exist $1 \leq p_i^2 \leq J$ so that (note that $N \leq N_{s^1-1}^{J(n+1)-p^1}$)

$$\begin{aligned} \theta_{J(n+1)} &\leq \sum_i \frac{\theta^{p^1}}{(1+\varepsilon)} \frac{1}{\phi_{p_i^2}(1+\varepsilon)} \|F_i x_{s^1}^{J(n+1)-p^1}\|_{N, p_i^2} + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{T}(x_1^{J(n+1)}, p^1)\} \\ &\leq \sum_i \frac{\theta^{p^1}}{(1+\varepsilon)} \frac{1}{\phi_{p_i^2}(1+\varepsilon)} \|F_i x_{s^1}^{J(n+1)-p^1}\|_{N_{s^1-1}^{J(n+1)-p^1}, p_i^2} + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum_{x_s^k \in \mathcal{T}(x_1^{J(n+1)}, p^1)} \delta_s^k. \end{aligned}$$

Then by corollary 4.14 (1), for each i there exists $s_i^2 \in \mathbf{N}$ so that $\text{ran}(x_{s_i^2}^{J(n+1)-p^1-p_i^2}) \subseteq F_i$ and also family of intervals $(E_{i,j})_{j=1, \dots, N_{s_i^2-1}^{J(n+1)-p^1-p_i^2}} \subseteq \text{ran}(x_{s^1}^{J(n+1)-p^1})$ so that

$$\begin{aligned} \theta_{J(n+1)} &\leq \sum_i \frac{\theta^{p^1}}{(1+\varepsilon)} \frac{1}{\phi_{p_i^2}(1+\varepsilon)} \left(\theta_{p_i^2} \|x_{s_i^2}^{J(n+1)-p^1-p_i^2}\|_{N_{s_i^2-1}^{J(n+1)-p^1-p_i^2}, 0} + \sum \left\{ \frac{\varepsilon_s^k}{N_{s-1}^k} : x_s^k \in \mathcal{T}_{F_i}(x_{s^1}^{J(n+1)-p^1}, p_i^2) \right\} \right) \\ &\quad + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{T}(x_1^{J(n+1)}, p^1)\} \leq \\ &\quad \sum_i \sum_{j=1}^{N_{s_i^2-1}^{J(n+1)-p^1-p_i^2}} \frac{\theta^{p^1+p_i^2}}{(1+\varepsilon)^2} \|E_{i,j} x_{s_i^2}^{J(n+1)-p^1-p_i^2}\| + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{S}\} \end{aligned}$$

where $\mathcal{S} = \mathcal{T}(x_1^{J(n+1)}, p^1) \cup \cup_i \cup \{\mathcal{T}(x_t^{J(n+1)-p^1-1}, p_i^2) : \text{ran}(x_t^{J(n+1)-p^1-1}) \subseteq F_i\}$. We increase $\mathcal{A}$ by including every node $x_s^{J(n+1)-p^1-p_i^2-1}$ which is split by some $E_{i,j}$ and minimally shrink the $E_{i,j}$'s to get intervals $(F_{i,j})$ which don't split the $x_s^{J(n+1)-p^1-p_i^2-1}$'s. Thus

$$\theta_{J(n+1)} \leq \sum_i \sum_j \frac{\theta^{p^1+p_i^2}}{(1+\varepsilon)^2} \|F_{i,j} x_{s_i^2}^{J(n+1)-p^1-p_i^2}\| + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{S}\}.$$

For every i, j there exists $1 \leq p_{i,j}^3 \leq J$ so that we have (note also that $N \leq N_{s_i^2-1}^{J(n+1)-p^1-p_i^2}$)

$$\begin{aligned} \theta_{J(n+1)} &\leq \sum_i \sum_j \frac{\theta^{p^1+p_i^2}}{(1+\varepsilon)^2} \frac{1}{\phi_{p_{i,j}^3}(1+\varepsilon)} \|F_{i,j} x_{s_i^2}^{J(n+1)-p^1-p_i^2}\|_{N, p_{i,j}^3} + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{S}\} \\ &\leq \sum_i \sum_j \frac{\theta^{p^1+p_i^2}}{(1+\varepsilon)^2} \frac{1}{\phi_{p_{i,j}^3}(1+\varepsilon)} \|F_{i,j} x_{s_i^2}^{J(n+1)-p^1-p_i^2}\|_{N_{s_i^2-1}^{J(n+1)-p^1-p_i^2}, p_{i,j}^3} + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} \\ &\quad + \sum \{\delta_s^k : x_s^k \in \mathcal{S}\}. \end{aligned}$$

By corollary 4.14 (1), for each i, j there exists $s_{i,j}^3 \in \mathbb{N}$ so that

$$\begin{aligned} \theta_{J(n+1)} &\leq \sum_i \sum_j \frac{\theta^{p^1+p_i^2}}{(1+\varepsilon)^2} \frac{1}{\phi_{p_{i,j}^3}(1+\varepsilon)} \left(\theta_{p_{i,j}^3} \|x_{s_{i,j}^3}^{J(n+1)-p^1-p_i^2-p_{i,j}^3}\|_{N_{s_{i,j}^3-1}^{J(n+1)-p^1-p_i^2-p_{i,j}^3,0}} \right. \\ &\quad \left. + \sum \left\{ \frac{\varepsilon_s^k}{N_{s-1}^k} : x_s^k \in \mathcal{T}_{F_{i,j}}(x_{s_i^2}^{J(n+1)-p^1-p_i^2}, p_{i,j}^3) \right\} \right) + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{S}\} \\ &\leq \sum_i \sum_j \frac{\theta^{p^1+p_i^2+p_{i,j}^3}}{(1+\varepsilon)^3} \|x_{s_{i,j}^3}^{J(n+1)-p^1-p_i^2-p_{i,j}^3}\|_{N_{s_{i,j}^3-1}^{J(n+1)-p^1-p_i^2-p_{i,j}^3,0}} + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{S}'\} \end{aligned}$$

for some $\mathcal{S}' \subseteq \mathcal{T}$. We continue passing to lower levels of the tree until we obtain $Jn \leq p^1 + p_i^2 + \dots + p_{i,\dots,k}^r \leq J(n+1) - 1$. On each branch of the tree we stop when this is satisfied. Thus we get an estimate of the following form ($\mathcal{A}$ increases to contain the x_s^k 's that are split)

$$\begin{aligned} \theta_{J(n+1)} &\leq \sum_{i,\dots,k} \sum \frac{\theta^{p^1+p_i^2+\dots+p_k^r}}{(1+\varepsilon)^r} \|x_{s_{i,\dots,k}^r}^{J(n+1)-p^1-p_i^2-\dots-p_{i,\dots,k}^r}\|_{N_{s_{i,\dots,k}^r-1}^{J(n+1)-p^1-p_i^2-\dots-p_{i,\dots,k}^r,0}} \\ &\quad + 2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} + \sum \{\delta_s^k : x_s^k \in \mathcal{W}\} \end{aligned}$$

for some $\mathcal{W} \subseteq \mathcal{T}$, where the first “ $\sum$ ” is taken over all branches on which we have $Jn \leq p^1 + p_i^2 + \dots + p_{i,\dots,k}^r \leq J(n+1) - 1$. By remark 4.6 (3) we have that $2 \sum \{\|x_s^k\| : x_s^k \in \mathcal{A}\} < \varepsilon \theta_{J(n+1)}$. Also $\sum \{\delta_s^k : x_s^k \in \mathcal{W}\} < \varepsilon \theta_{J(n+1)}$. Thus

$$\theta_{J(n+1)} \leq \frac{\theta^{Jn}}{(1+\varepsilon)^n} \sum_{i,\dots,k} \|x_{s_{i,\dots,k}^r}^{J(n+1)-p^1-p_i^2-\dots-p_{i,\dots,k}^r}\|_{N_{s_{i,\dots,k}^r-1}^{J(n+1)-p^1-p_i^2-\dots-p_{i,\dots,k}^r,0}} + 2\varepsilon \theta_{J(n+1)}.$$

Since $\|\cdot\|_{n,0} \leq \frac{1}{\theta_1} \|\cdot\|$, the vectors $x_{s_{i,\dots,k}^r}^{J(n+1)-p^1-p_i^2-\dots-p_{i,\dots,k}^r}$'s have disjoint support and their level in the tree is at least 1, by the triangle inequality we obtain

$$\theta_{J(n+1)} \leq \frac{\theta^{Jn}}{\theta_1(1+\varepsilon)^n} + 2\varepsilon \theta_{J(n+1)} \Leftrightarrow 1 \leq \frac{1}{(1+\varepsilon)^n \theta_1 \phi_{J(n+1)}} + 2\varepsilon$$

which is a contradiction. $\square$

Proof of theorem 4.4 Let $\varepsilon > 0$ be arbitrary. By lemma 4.15 we can find a normalized block sequence (x_i) in Y and an increasing sequence $(\bar{j}_i)$ of integers, $\bar{j}_1 = 1$, so that if $N_0 = 1$ and $N_i = \max(\text{ran}(x_i))$ w.r.t. (e_s) then for every $i \in \mathbb{N}$ we have

$$\begin{aligned} \forall p = 1, \dots, \bar{j}_i, \quad & \|x_i\|_{N_{i-1},p} < \phi_p(1+\varepsilon) \text{ and} \\ \forall p \geq \bar{j}_{i+1}, \quad & \|x_i\|_{N_{i-1},p} < \varepsilon. \end{aligned}$$

Apply corollary 4.14 for (x_i) , ε , $N = 1$ and $M = j$ (and appropriate (ε_i^k)) to obtain x , a $(j, (\varepsilon_i^k), 1)$ average of (x_i) w.r.t. (e_i) with admissible averaging tree $(x_i^k)_{k=0,i=1}^{j,N^k}$ of (x_i) and maximum coordinates $(N_i^k)_{k=1,i=0}^{j,N^k}$ w.r.t. (e_i) . For $i = 1, \dots, N^0$ if $x_i^0 = x_s$ then define $j_i = \bar{j}_s$. Then $j_1 < \dots < j_{N^0}$ and for $i = 1, \dots, N^0$ we have

$$\begin{aligned} \forall p = 1, \dots, j_i, \quad & \|x_i^0\|_{N_{i-1}^0,p} < \phi_p(1+\varepsilon) \text{ and} \\ \forall p \geq j_{i+1}, \quad & \|x_i^0\|_{N_{i-1}^0,p} < \varepsilon. \end{aligned}$$

Note (by remark 4.6 (2)) that x_1^j is j -admissible w.r.t. (x_i) and by corollary 4.14 (2) there exist $m \in \mathbf{N}$, intervals $F_1 < \dots < F_m$ which don't split the x_s^0 's, and $(p_\ell)_{\ell=1}^m \subset \mathbf{N}$ with $p_\ell \geq j$ for all ℓ such that

$$\|x\| \leq \max \left(\bigcup_{\ell=1}^m \left\{ \frac{\theta_{p_\ell}}{\theta_{p_\ell-j}} \|x_s^0\|_{N_{s-1, p_\ell-j}^0} : \text{ran}(x_s^0) \subseteq F_\ell \right\}^* \right) + \varepsilon.$$

For each $\ell = 1, \dots, m$ if $p_\ell > j$ then there exists exactly one $m_\ell \in \mathbf{N}$ such that $j_{m_\ell} \leq p_\ell - j < j_{m_\ell+1}$. We shall use the obvious remark that if $A \subseteq [0, \infty)$ is a finite non-empty set and $a \in A$ then $\max(A^*) \leq \max(A \setminus \{a\})$. If $p_\ell = j$ then $\theta_{p_\ell}/\theta_{p_\ell-j} = \theta_j$ and we note that $\|x_s^0\|_{N_{s-1,0}^0} \leq \frac{1}{\theta_1} \|x_s^0\| = \frac{1}{\theta_1}$. Thus

$$\|x\| \leq \max \left(\bigcup_{\{\ell: p_\ell > j\}} \left\{ \frac{\theta_{p_\ell}}{\theta_{p_\ell-j}} \|x_s^0\|_{N_{s-1, p_\ell-j}^0} : \text{ran}(x_s^0) \subseteq F_\ell, s \neq m_\ell \right\} \cup \left\{ \frac{\theta_j}{\theta_1} \right\} \right) + \varepsilon.$$

Let $\text{ran}(x_s^0) \subseteq F_\ell$ and $p_\ell > j$. If $s < m_\ell$ we have $j_{s+1} \leq j_{m_\ell} \leq p_\ell - j$ and so $\|x_s^0\|_{N_{s-1, p_\ell-j}^0} < \varepsilon$. If $s > m_\ell$ we have $j_s \geq j_{m_\ell+1} > p_\ell - j$ and so $\|x_s^0\|_{N_{s-1, p_\ell-j}^0} < \phi_{p_\ell-j}(1 + \varepsilon)$. Note that

$$\frac{\theta_{p_\ell}}{\theta_{p_\ell-j}} \phi_{p_\ell-j} = \theta^j \phi_{p_\ell}$$

and therefore

$$\|x\| \leq \theta^j \sup_{p \geq j} \phi_p (1 + \varepsilon) \vee \frac{\theta_j}{\theta_1} + 2\varepsilon.$$

Note (by remark 4.6) that we can write $x = \sum_F a_i x_i$ for some set $F \in S_j$ where $a_i > 0$ for all $i \in F$ and $\sum_{i \in F} a_i = 1$. Therefore $\delta_j(Y) \leq \|x\|$ and since $\varepsilon > 0$ is arbitrary we obtain the result. $\square$

Note that theorem 4.4 does not necessarily give the best possible estimate for $\delta_j(Y)$. Indeed if $\theta_n = 2^{-n}$ for all n then $T = T(\theta_n, S_n)_\mathbf{N}$ and for all $Y \prec T$, $\delta_j(Y) = 2^{-j}$ [OTW]. Yet theorem 4.4 only gives $\delta_j(Y) \leq 2^{-j+1}$. However we have the following estimate which does yield the proper estimate for Tsirelson's space.

Theorem 4.16 *Let $X = T(\theta_n, S_n)_\mathbf{N}$ be regular. Then for all $Y \prec X$ and $j \in \mathbf{N}$ we have*

$$\delta_j(Y) \leq \theta^j \sup_{p \geq j} \frac{\phi_p}{\phi_{p-j}}.$$

Proof Let $Y \prec X$, $j \in \mathbf{N}$ and $\varepsilon > 0$. Since Y contains ℓ_1^n 's uniformly, for all $N \in \mathbf{N} \exists y \in Y$ with $1 = \|y\| \leq \|y\|_{N,0} \leq 1 + \varepsilon$. (see eg [OTW] proposition 2.7). Therefore we may choose inductively a normalized block sequence (x_i) in Y so that for $i \in \mathbf{N}$ if $N_i = \max(\text{ran}(x_i^0))$ w.r.t. (e_i) ($N_0 = 1$) then $\|x_i\|_{N_{i-1},0} \leq 1 + \varepsilon$. Note then that for every $i, p \in \mathbf{N}$, $\|x_i\|_{N_{i-1},p} \leq \|x_i\|_{N_{i-1},0} \leq 1 + \varepsilon$. Apply corollary 4.14 (for an appropriate sequence (ε_i^k)) to obtain x a $(j, (\varepsilon_i^k), 1)$ average of (x_i) w.r.t. (e_i) with admissible averaging tree $(x_i^k)_{k=0, i=1}^{j, N^k}$ of (x_i) and maximum coordinates $(N_i^k)_{k=0, i=0}^{j, N^k}$ w.r.t. (e_i) . Note then that for every $i, p \in \mathbf{N}$ we have that $\|x_i^0\|_{N_{i-1},p} \leq 1 + \varepsilon$. By corollary 4.14 (2) there exist $m \in \mathbf{N}$, $F_1 < \dots < F_m$ intervals in $\mathbf{N}$ which don't split the x_i^0 's and integers $(p_\ell)_{\ell=1}^m$ with $p_\ell \geq j$ for all ℓ , such that

$$\|x\| \leq \max \left\{ \frac{\theta_{p_\ell}}{\theta_{p_\ell-j}} \|x_i^0\|_{N_{i-1}, p_\ell-j} : \ell = 1, \dots, m, \text{ran}(x_i^0) \subseteq F_\ell \right\} + \varepsilon \leq \theta^j \sup_{p \geq j} \frac{\phi_p}{\phi_{p-j}} (1 + \varepsilon) + \varepsilon$$

and the result follows since $\varepsilon > 0$ is arbitrary. $\square$

To estimate $\delta_j(Y)$ for $Y = X$ is easy as we see from the next

Theorem 4.17 *Let $X = T(\theta_n, S_n)_{n \in \mathbb{N}}$ be regular. Then for all $j \in \mathbb{N}$ we have $\delta_j(X) = \theta_j$.*

Proof Let $j \in \mathbb{N}$ and $\varepsilon > 0$. Apply corollary 4.14 for $(x_i) = (e_i)$, $M = j$, $N = 1$ and an appropriate sequence (ε_i^k) , to obtain x , a $(j, (\varepsilon_i^k), 1)$ average of (e_i) w.r.t. (e_i) with admissible averaging tree $(x_i^k)_{k=0, i=1}^{j, N^k}$ and maximum coordinates $(N_i^k)_{k=0, i=0}^{j, N^k}$ w.r.t. (e_i) . Then by (2) there exists $m \in \mathbb{N}$, $F_1 < \dots < F_m$ intervals in $\mathbb{N}$ and integers $(p_\ell)_{\ell=1}^m$ with $p_\ell \geq j$ for all ℓ , such that

$$\|x\| \leq \max\left\{\frac{\theta_{p_\ell}}{\theta_{p_\ell-j}} \|x_i^0\|_{N_{i-1}^0, p_\ell-j} : \ell = 1, \dots, m, \text{ran}(x_i^0) \subseteq F_\ell\right\} + \varepsilon.$$

Since $(x_i^0)_{i=1}^{N^0}$ is a subsequence of (e_i) , we have $\|x_i^0\|_{N_{i-1}^0, p_\ell-j} = \theta_{p_\ell-j}$ for every $i = 1, \dots, N^0$ and $\ell = 1, \dots, m$. Thus $\|x\| \leq \max_{1 \leq \ell \leq m} \theta_{p_\ell} + \varepsilon$. Since the sequence (θ_i) is decreasing we have $\|x\| \leq \theta_j + \varepsilon$. Since $\text{supp}(x) \in S_j$ and $\varepsilon > 0$ is arbitrary we obtain the result. $\square$

Question If $X = T(\theta_n, S_n)_{\mathbb{N}}$ is a regular mixed Tsirelson space and $Y \prec X$ is $\delta_j(Y) = \theta_j$ for every $j \in \mathbb{N}$?
